

TRUE SALAMANDERS AND NEWTS (SALAMANDRIDAE)

HABITAT

A generalist species, but with a preference for largely open landscapes, including agricultural land. During the aquatic period common in flooded fields, but mostly more permanent ponds, lakes, springs and slow-flowing streams are used. Rarely in brackish water.

BIOLOGY

During terrestrial phase usually encountered underneath logs or stones, but active at night following periods of rain. Usually hibernates on land in N of range, but sometimes in water. Active between February and November in most areas, but this varies widely with climate and sometimes active throughout the year. Reproduction may start

in winter in S of range but more typically around March in N of range. Males court females by fanning pheromones from their cloaca towards potential mates using their tail-tip. A spermatophore is released and absorbed by the female. Females deposit up to 300 eggs individually, often folding aquatic vegetation around each egg. Freshly metamorphosed juveniles may be encountered in summer. At high elevations or in cold shady waters, larvae may spend the winter in the water to complete metamorphosis the subsequent year. Feeds on various arthropods, snails and worms, but also on the larvae of other amphibians. Like other newts, may be seen feeding on frog spawn in spring.
