Bassham, Jose L Crespo, 2015-05-15 Autophagy also known as macroautophagy is an evolutionarily conserved process by
which cytoplasmic components are nonselectively enclosed within a double membrane vesicle known as the autophagosome
and delivered to the vacuole for degradation of toxic components and recycling of needed nutrients This catabolic process is
required for the adequate adaptation and response of the cell and correspondingly the whole organism to different types of
stress including nutrient starvation or oxidative damage Autophagy has been extensively investigated in yeasts and mammals
but the identification of autophagy related ATG genes in plant and algal genomes together with the characterization of
autophagy deficient mutants in plants have revealed that this process is structurally and functionally conserved in
photosynthetic eukaryotes Recent studies have demonstrated that autophagy is active at a basal level under normal growth
in plants and is upregulated during senescence and in response to nutrient limitation oxidative stress salt and drought
conditions and pathogen attack Autophagy was initially considered as a non selective pathway but numerous observations
mainly obtained in yeasts revealed that autophagy can also selectively eliminate specific proteins protein complexes and
organelles Interestingly several types of selective autophagy appear to be also conserved in plants and the degradation of
protein aggregates through specific adaptors or the delivery of chloroplast material to the vacuole via autophagy has been
reported This research topic aims to gather recent progress on different aspects of autophagy in plants and algae We
