

THEORY OF OPERATION

Basic Air Conditioning System

Refrigerant system divided into two halves

There are two basic system configurations: systems that use expansion valves and systems that use orifice tubes. For both of these systems, the refrigerant is divided into a high-pressure side and a low-pressure side – the dividing points are the compressor and the expansion valve or orifice tube.

In the expansion valve system, the high side begins at the compressor, continues through the condenser, on through the receiver/drier and ends at the expansion valve. The low side begins where the high side left off – at the expansion valve. From there it continues through the evaporator and ends at the compressor.

In an orifice tube system, the high side again begins at the compressor, continues through the condenser, and ends at the orifice tube. The low side begins where the high side left off – at the orifice tube. From there it continues through the evaporator, through the accumulator, and again ends at the compressor.

Let's take a look at how each part in the system affects the refrigerant, to allow it to remove heat from the passenger compartment.

Compressor starts refrigerant flow

The compressor is nothing more than a pump (a gas pump, not a liquid pump); its job is to move the refrigerant through the system. When restricted, that flow creates the pressure differential in the system. The compressor is mounted on the engine, and a drive belt from the engine turns the compressor clockwise, working the compressor pistons back and forth. The back-and-forth movement of the pistons is what draws the refrigerant in on the low side and pumps it out on the high side.

When the compressor turns, it pushes all of the refrigerant in the system toward the high side of the expansion valve. At the same time, it pulls all the refrigerant it can from the evaporator side of the expansion valve.

The air conditioning system is divided into two sides: the high side and the low side. The difference in the flow of refrigerant through the system.

The compressor turns the refrigerant through the system in a closed loop.

THEORY OF OPERATION

Expansion valve restricts the refrigerant flow

The expansion valve is a restricting orifice that sits between the high side and the low side of the refrigerant system. Whenever you place a restriction in the flow of a closed system, you create a pressure differential between the two sides of the orifice.

The movement of the refrigerant with the expansion valve orifice restricting its flow creates the high side and the low side of the system.

A small amount of high-pressure refrigerant passes through the orifice in the expansion valve, and as it reaches the low pressure in the evaporator, the refrigerant's pressure drops to about 30 PSI (207 kPa).

The expansion valve restricts the flow of refrigerant to provide the pressure differential the system needs to be able to absorb heat from the passenger compartment and deliver it outside.
