

Lab 10: Molecular PCR and ELISA

Background Information

Each week you completed exercises related to the following concepts and laboratory techniques: immunology (IMM), DNA sequencing (DNA), and the polymerase chain reaction (PCR). Today you will gain hands-on experience performing a Polymerase Chain Reaction (PCR) and an enzyme-linked immunosorbent assay (ELISA).

PCR is a versatile technique that has been useful in detecting and identifying infectious etiologic agents associated with AIDS. In combination, specific antibody-based infection, when the disease process has been well along (IMM), together with PCR can be used to detect most infections. This provides an important method for understanding the development and spread of the virus. Immunology teaches that PCR cannot be used to detect past infections because it only provides a snapshot of the body's response at a specific moment in time.

Part I: PCR

Overview of PCR

Polymerase chain reaction (PCR) is a method for amplifying an entire viral infectious agent (HIV, CMV, etc.) or individual gene PCR isolates specific target viral sequences, and through the polymerase chain reaction (PCR) is widely used in other diagnostic laboratory research areas. In order to amplify a specific region of the genome, scientists use primers that bind complementary with each particular sequence (oligonucleotides) (Figure 1), and the resulting double-stranded, copied target sequence undergoes exponential amplification to produce a large number of copies of the target (Figure 2).

Figure 1: PCR primers. The primers are single-stranded DNA, usually between 18-24 bases long, which attach to individual genomic sites at the complementary sequences. The primers are designed to flank the target (indicated above) at both ends.
