

Soil thermal resistivity

Thermal resistivity depends mainly on soil composition (i.e. mineral, organics), texture (i.e. particle size grading), water content, and dry density. This complex interrelationship does not lend itself to a simple formula; testing must be carried out on any given soil to determine its resistivity.

You want high water content and high soil density (see next slide).

Air has a high thermal resistivity and therefore does not dissipate heat very well. Water dissipates heat better.

Soil with lowest thermal resistivity has maximum amount of soil grains & water.
