Diane C Bassham, Jose L Crespo, 2015-05-15 Autophagy also known as macroautophagy is an evolutionarily conserved process
by which cytoplasmic components are nonselectively enclosed within a double membrane vesicle known as the
autophagosome and delivered to the vacuole for degradation of toxic components and recycling of needed nutrients This
catabolic process is required for the adequate adaptation and response of the cell and correspondingly the whole organism to
different types of stress including nutrient starvation or oxidative damage Autophagy has been extensively investigated in
yeasts and mammals but the identification of autophagy related ATG genes in plant and algal genomes together with the
characterization of autophagy deficient mutants in plants have revealed that this process is structurally and functionally
conserved in photosynthetic eukaryotes Recent studies have demonstrated that autophagy is active at a basal level under
normal growth in plants and is upregulated during senescence and in response to nutrient limitation oxidative stress salt and
drought conditions and pathogen attack Autophagy was initially considered as a non selective pathway but numerous
observations mainly obtained in yeasts revealed that autophagy can also selectively eliminate specific proteins protein
complexes and organelles Interestingly several types of selective autophagy appear to be also conserved in plants and the
degradation of protein aggregates through specific adaptors or the delivery of chloroplast material to the vacuole via
autophagy has been reported This research topic aims to gather recent progress on different aspects of autophagy in plants
and algae We welcome all types of articles including original research methods opinions and reviews that provide new
